HIGHLIGHTS

This surveillance report, published by the National Institute on Alcohol Abuse and Alcoholism (NIAAA), presents trends in liver cirrhosis mortality in the United States. Data on the underlying cause of death were compiled from public use data tapes published annually by the National Center for Health Statistics (NCHS). Population data provided by the U.S. Census Bureau are used as denominators to calculate mortality rates.

Overall cirrhosis mortality in the United States increased steadily following the end of Prohibition in 1933 until 1973, when the age-adjusted death rate peaked at 18.1 deaths per 100,000 population. Cirrhosis mortality then began an almost steady decline that has continued through 2001, the most recent year for which data are available. The following are highlights of liver cirrhosis mortality trends from the early 1970s through 2001:

Cirrhosis Mortality in 2001

- In 2001 liver cirrhosis was the 12th leading cause of death in the United States, with a total of 27,485 deaths, 480 more than in 2000.
- The crude death rate from all cirrhosis and from alcohol-related cirrhosis in 2001 remained the same as in 2000, 9.6 and 4.3 deaths per 100,000 population, respectively.
- Among all cirrhosis deaths in 2001, 44.4 percent were alcohol-related. The proportion of alcohol-related cirrhosis was highest (63.8 percent) among decedents aged 25 to 34.
- The age-adjusted death rate from all liver cirrhosis for White Hispanic males was 2.0 times the rate for White non-Hispanic males and 1.7 times the rate for Black non-Hispanic males. The age-adjusted death rate from all liver cirrhosis for White Hispanic females was 1.5 times the rate for White non-Hispanic females and 1.6 times the rate for Black non-Hispanic females.

Cirrhosis Mortality Trends

- While the age-adjusted all-cause mortality rate declined by 30.1 percent from 1970 to 2001, the age-adjusted death rate from all liver cirrhosis declined for the same period by 45.5 percent, from 17.8 to 9.7 deaths per 100,000 population. Rates for White males, Black males, White females, and Black females declined by 42.7, 62.4, 39.3, and 71.0 percent, respectively.
- The age-adjusted death rate from all liver cirrhosis for males was consistently more than twice the rate for females, regardless of race.
- The age-adjusted death rate from alcohol-related liver cirrhosis declined by 31.7 percent, from 6.3 deaths per 100,000 population in 1970 to 4.3 deaths per 100,000 population in 2001. Rates for White males, Black males, White females, and Black females declined by 22.4, 59.4, 29.0, and 69.6 percent, respectively.
- From 1970 through 2001 age-specific death rates from liver cirrhosis decreased among population groups below age 75. Over this same period there were fluctuations in cirrhosis mortality rates that showed slight increases among population groups aged 75 and older.

Healthy People 2010 Objectives

- One of the Healthy People 2010 objectives is to reduce liver cirrhosis mortality to no more than 3.0 deaths per 100,000 population. To achieve this goal, the age-adjusted death rates from cirrhosis must decrease by 12 percent per year from 2001 through 2010.

INTRODUCTION

This surveillance report on liver cirrhosis is one of a series of four reports published annually to monitor trends in alcohol consumption and alcohol-related morbidity and mortality in the United States. These surveillance reports are prepared by the Alcohol Epidemiologic Data System (AEDS), Division of Epidemiology and Prevention Research, NIAAA, and are intended to be useful to researchers, policymakers, and other professionals interested in alcohol abuse and its long-term effects. The data also are essential in assessing changes toward meeting the Nation's health promotion and disease prevention objective to reduce liver cirrhosis mortality as stated in Healthy People 2010 (Department of Health and Human Services [DHHS] 2000).

Cirrhosis of the liver is an outcome of a variety of causes including alcohol consumption, exposure to various drugs and toxic chemicals, viral hepatitis, and other viral and infectious diseases (Dufour et al. 1993). Based on a literature review, it has been estimated that alcohol consumption is a major contributor in 41 to 95 percent of deaths from cirrhosis and the related condition of alcoholic hepatitis (Day 1977). Based on these percentages, 11,269 to 26,111 of the cirrhosis deaths in 2001 may be attributed to excessive alcohol use.

The level and duration of alcohol consumption are important determinants in the development of liver pathology. As the primary site for detoxification of alcohol by oxidation to its metabolites, the liver can undergo the following pathologies: fatty liver, alcoholic hepatitis, and cirrhosis. The prognosis for patients with cirrhosis is highly unpredictable. Although some patients can benefit from a liver transplant, no method currently exists for repairing liver damage associated with cirrhosis. However, the consequences of this disease can be treated, and life can be prolonged, if patients with cirrhosis resulting from alcohol consumption abstain from further alcohol use. Thus, early

detection and prevention of further damage are important in prolonging life.

The coding scheme used in the United States to classify cause of death is the International Classification of Diseases (ICD), a statistical classification of disease and injury widely used by countries supporting mortality reporting systems. ICD codes allow the cause of death from cirrhosis to be related to alcohol or not related to alcohol. Because some stigma still exists for excessive alcohol use, physicians and other officials who certify causes of death may not identify alcohol in the case of a death from cirrhosis in an effort to protect family members. From 1970 to 2001, the proportion of all cirrhosis deaths coded as alcohol-related ranged from 36 to 48 percent (depending on year), even though some researchers believe alcohol may contribute to a substantially higher proportion of all deaths from cirrhosis (Haberman and Weinbaum 1990; Powell and Klatskin 1968). For this reason, this surveillance report examines all cirrhosis deaths, as well as those that are explicitly coded as alcohol-related.

DATA AND MEASURES

Sources and Limitations of Data

Death counts and rates in this report are based on a single underlying cause for each death, defined as "the disease or injury which initiated the train of morbid events leading directly or indirectly to death or circumstances of the accident or violence which produced the fatal injury" (NCHS 1982). This approach is consistent with other mortality statistics reported by NCHS.

Cirrhosis death records for 1970 through 2001 were extracted from public use mortality computerized data files produced by NCHS. With the exception of data files for 1972, these files contain individual records for each death occurring in the United States, and in 1972 the files contained a 50-percent sample of all U.S. deaths. The deaths counted in this report are for U.S. residents only. Deaths of foreign residents in the United States are not counted. Mortality statistics for the years 1910 through

1969 were taken from special reports published by NCHS, as summarized and described in an NIAAA data reference manual on cirrhosis mortality (NIAAA 1985). These reports were prepared from numbers obtained through States' death registration offices. Prior to 1933 not all States collected death registration information. The changing number of death registration States impedes the process of obtaining comparable mortality data for the United States prior to 1933.

Population data for 2000 and 2001 came from bridged-race Vintage 2002 postcensal estimates of the resident population of the United States, developed for NCHS by the U.S. Census Bureau (NCHS 2003a). Population data for years 1990 through 1999 came from bridged-race intercensal resident population estimates developed for NCHS by the U.S. Census Bureau (NCHS 2003b). Population data for 1970 through 1989 came from estimates developed for the National Cancer Institute (NCI) by the U.S. Census Bureau (NCI 2002). Population data for 1910 through 1969 were estimated using the numbers of cirrhosis deaths and the age-specific death rates reported in an NIAAA data reference manual on cirrhosis mortality (NIAAA 1985).

Definitions and Subclassifications of Liver Cirrhosis

During the period for which mortality statistics are shown in this report, cause of death was classified according to nine different revisions of the ICD. The ICD is revised periodically to reflect progress in medical knowledge, with later revisions generally providing greater specificity of coding.

The eighth (NCHS 1968), ninth (World Health Organization [WHO] 1978), and tenth (WHO 1992) revisions of the ICD (introduced in 1968, 1979, and 1999, respectively) provide for coding categories of cirrhosis with and without mention of alcohol. The eighth revision, abbreviated "ICDA-8," was specially adapted for use in the United States. The ninth revision, ICD-9, uses different categories for cirrhosis than ICDA-8. The tenth revision, ICD-10, uses twice as many categories for

cirrhosis as ICD-9. To examine trends for comparable diseases from 1970 through 2001, ICD-9 and ICD-10 categories must be matched and recoded to those consistent with ICDA-8 categories. The relevant crosswalk of the three ICD revisions, developed by AEDS staff in collaboration with NIAAA's former Division of Biometry and Epidemiology (DBE), is shown in the table on the following page. As can be seen under ICD-10 in the crosswalk table, AEDS includes portal hypertension (ICD code K76.6) and change of fatty liver not elsewhere classified (ICD code K76.0) among cirrhosis deaths. Because NCHS counts only ICD codes K70, K73, and K74 as liver cirrhosis, AEDS' numbers are slightly larger than those reported by NCHS.

With the introduction of ICD-10 for 1999 data came changes in rules for selecting the underlying cause of death and new categories. These new rules and categories may contribute to observed changes in the number of deaths from liver cirrhosis. Anderson et al. (2001) conducted a comparability study estimating that the use of ICD-10 would classify an additional 3.67 percent of deaths as due to cirrhosis when compared with ICD-9. Readers should keep this in mind when examining trends involving data from 1999 and later years.

Race or Ethnicity of Decedent

Data are presented in this report by White and Black race categories, with other races such as American Indian/Alaska Native and Asian/Pacific Islander included in the "all races" category but not shown separately. Vital statistics data also provide information on the ethnicity of decedents (i.e., Mexican, Puerto Rican, Cuban, Central or South American, other or unknown Hispanic, or non-Hispanic). However, prior to 1991, substantial proportions of decedents were missing ethnic identification, and Hispanic origin measures were not usable. Beginning with the 1999 issue of this report (Saadatmand et al. 1999), trend data on Hispanic origin were presented for the years of 1991 and later.

The first year in which all 50 States and the District of Columbia included Hispanic origin

of decedents on their death certificates was 1997. In 2001 only 0.4 percent of cirrhosis decedents had an “unknown” classification for Hispanic origin. From 1991 through 2001 the percentage of cirrhosis deaths with Hispanic origin unknown was less than 2 percent for both Black and White decedents. The tables and figures showing data based on Hispanic origin excluded decedents for whom Hispanic origin could not be determined. Readers are cautioned that rates calculated for Black Hispanics are unreliable because of the small number of cirrhosis deaths in this population subgroup.

METHODS

Statements of disease frequency, expressed as the number of deaths due to liver cirrhosis, have little epidemiologic usefulness because such information does not permit either comparisons of mortality among various population subgroups or the description of trends over time. For epidemiologic purposes, death rates are used to compare the frequency of death from a disease or condition. The following measures of disease frequency are used in this report to assess trends in liver cirrhosis mortality:

Crosswalk of ICD-10 codes to ICD-9 codes and ICDA-8 codes

ICD-10	ICD-9	ICDA-8
K70.0 Alcoholic fatty liver	571.0 Alcoholic fatty liver	571.0 Alcohol-related liver cirrhosis
K70.1 Alcoholic hepatitis	571.1 Acute alcoholic hepatitis	
K70.2 Alcoholic fibrosis and sclerosis of liver	571.2 Alcoholic cirrhosis of liver	
K70.3 Alcoholic cirrhosis of liver		
K70.9 Alcoholic liver disease, unspecified	571.3 Alcoholic liver damage, unspecified	
K70.4 Alcoholic hepatic failure ¹	303 & Alcohol dependence 572.8 syndrome and chronic hepatic failure	
K73.0 Chronic persistent hepatitis, not elsewhere classified (n.e.c.) K73.1 Chronic lobular hepatitis, n.e.c. K73.2 Chronic active hepatitis, n.e.c. K73.8 Other chronic hepatitis, n.e.c. K73.9 Chronic hepatitis, unspecified	571.4 Chronic hepatitis	571.8 Specified liver cirrhosis without mention of alcohol
K74.3 Primary biliary cirrhosis K74.4 Secondary biliary cirrhosis K74.5 Biliary cirrhosis, unspecified	571.6 Biliary cirrhosis	
K76.0 Fatty (change of) liver, n.e.c. ²	571.8 Other chronic nonalcoholic liver disease	
K76.6 Portal hypertension ²	572.3 Portal hypertension	
K74.0 Hepatic fibrosis K74.2 Hepatic fibrosis with hepatic sclerosis K74.6 Other and unspecified cirrhosis of liver	571.5 Cirrhosis of the liver without mention of alcohol	571.9 Unspecified liver cirrhosis without mention of alcohol
K74.1 Hepatic sclerosis	571.9 Unspecified liver cirrhosis without mention of alcohol	

¹ A new title in ICD-10 that requires the coexistence of two ICD-9 codes.

² Not defined as liver cirrhosis by NCHS.

- Unadjusted (or crude) death rates.—Unadjusted (or crude) death rates are summary measures calculated by dividing the total number of deaths due to cirrhosis (or subcategories) in the population in a certain year by the total number of individuals in that population in that year (i.e., population at risk). Problems can arise when comparing crude rates between various years to assess any change in mortality over time because the populations at risk may be different with respect to an underlying characteristic such as age, race, or sex. For example, an older population tends to have a higher rate of death for a target disease than a younger population because death from disease is more common in an aging population. In this case, rates in different populations should be assessed by comparing age-specific rates or age-adjusted rates.
- Age-specific death rates.—Age-specific death rates for any year refer to the number of deaths due to liver cirrhosis (or subcategories) in a defined age interval, divided by the total number of persons in that age interval. For a given age interval, examining age-specific rates for various years allows comparison of mortality rates among subgroups of the population that do not differ in their age distribution. Age-specific rates also provide a basis for detailed study of the variation of mortality rates among different age intervals in any single year.
- Age-adjusted death rates.—Age-adjusted death rates are statistically constructed summary rates that account for differences in mortality regardless of any difference in the age distribution between populations. Age adjustment assumes that populations have the same age distribution and applies a standard age distribution to calculate age-adjusted rates for various populations. Therefore, when comparing age-adjusted rates of two populations, any differences between the rates can no longer be due to the difference in the age distribution between the two populations. Age

adjustment is especially crucial for standardizing rates over many years because the U.S. population has grown progressively older in recent decades; without age adjustment, any apparent increases in unadjusted mortality rates for cirrhosis (or any other disease) could be caused by the fact that older people are more likely to die from disease.

The age distribution of the 1940 U.S. population was used as the standard to calculate all age-adjusted rates in previous issues of this surveillance report published before 2002. During the period from 1940 to 2000 the proportion of the U.S. population ages 65 years and older almost doubled (from 6.8 percent to 12.6 percent). To better reflect the characteristics of the current population age structure, the U.S. Department of Health and Human Services (1998) requires the use of the year 2000 standard population with mortality data for 1999 and later years. Therefore, beginning with the year 2002 issue of this report, all age-adjusted death rates have been computed based on the 2000 standard population, replacing the previously published rates based on the 1940 standard population.¹

Age-adjusted death rates presented in this report were computed by using 10-year age intervals of the enumerated population of the United States in 2000 as the standard population.

¹ Standard population age distribution:

Age group	Number	
	1940	2000
0 to 4 years	80,061	69,135
5 to 14 years	170,355	145,565
15 to 24 years	181,677	138,646
25 to 34 years	162,066	135,573
35 to 44 years	139,237	162,613
45 to 54 years	117,811	134,834
55 to 64 years	80,294	87,247
65 to 74 years	48,426	66,037
75 to 84 years	17,303	44,842
85+ years	2,770	15,508
All ages	1,000,000	1,000,000

Results from the age adjustment allow for meaningful comparison of similar rates over long periods of time or from different subpopulations. The basic procedure involves finding the expected number of deaths that would have existed if the age-specific rates for a particular year prevailed in a population whose age distribution was like that of the United States in 2000. This was accomplished by multiplying the specific rates for each age group by the population for the corresponding age group in the standard population. The age-adjusted mortality rate was calculated by adding the expected deaths for each age group and then dividing this sum by the total population taken as the standard.

— Because there was no information available on deaths by sex for 1910–1913 and 1917, age-adjusted death rates for males and females based on the year 2000 standard population were not calculated for those years.

1 Rates per 100,000 population computed by the direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 1940 and 2000.

2 Deaths based on a 50-percent sample.

3 Reporting States increased from 10 States and the District of Columbia in 1900 to the entire contiguous United States in 1933.

Table 2. Age-specific number of deaths, age-specific death rates, and age-adjusted death rates¹ from all liver cirrhosis by race, Hispanic origin, and sex, United States, 1970–2001.

Race, Hispanic origin ² , sex, and year	Number of deaths, by age group									Deaths per 100,000 population, by age group									Age-adjusted deaths per 100,000 population

— There were no deaths in this table cell.

¹ Rates per 100,000 population computed by direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 2000.

² Excludes deaths for which Hispanic origin was unknown and all 1991 through 1996 deaths from Oklahoma and New Hampshire where Hispanic origin was unknown in more than 90 percent of all cirrhosis deaths.

³ Includes deaths for which age of decedent was unknown; age-specific numbers of deaths may not sum to total.

4 Deaths based on a 50-percent sample.

5 Rates are not reliable due to the small number of cirrhosis deaths among Black Hispanics.

Table 3. Age-specific number of deaths, age-specific death rates, and age-adjusted death rates¹ from liver cirrhosis with and without mention of alcohol,
United States, 1970–2001.

Liver cirrhosis subcategory and year	Number of deaths, by age group									Deaths per 100,000 population, by age group									Age-adjusted deaths per 100,000 population

— There were no deaths in this table cell.

¹ Rates per 100,000 population computed by direct method, using as the standard population the age distribution of the total population of the United States as enumerated in 2000.

² Excludes deaths for which Hispanic origin was unknown and all 1991 through 1996 deaths from Oklahoma and New Hampshire where Hispanic origin was unknown in more than 90 percent of all cirrhosis deaths. Data on Hispanic origin not shown for years earlier than 1991.

³ Includes deaths for which Hispanic origin was unknown.

⁴ Rates are not reliable due to the small number of cirrhosis deaths among Black Hispanics.

⁵ Deaths based on a 50-percent sample.
